SURNAME $\qquad$ NAME.
1.- (1.2 points) Human body approximately contains 250 g of potassium from which $0.012 \%$ is ${ }^{40} \mathrm{~K}$, a beta emitter with $\mathrm{t}_{1 / 2}=1.25 \cdot 10^{9}$ y ( 1.311 MeV ). Answer succinctly the following questions:
a) ( 0.2 points) How changes Z and N in a beta emission process?
b) ( 0.2 points) Is it typical for nuclides with $\mathrm{N} / \mathrm{Z} \gg 1$ or $\mathrm{N} / \mathrm{Z} \ll 1$ ?
c) ( 0.2 points) What is activity? How is it related with the mean lifetime?
d) ( 0.6 points) Calculate the activity of ${ }^{40} \mathrm{~K}$ and the absorbed dose (in Gy) for a human ( 80 kg ) along all his life (80 y).
Data: $1 \mathrm{MeV}=10^{6} \mathrm{eV} ; 1 \mathrm{eV}=1.6 \cdot 10^{-19} \mathrm{~J} ; 1 \mathrm{y}=365.25 \mathrm{~d} ; \mathrm{N}_{\mathrm{A}}=6.022 \cdot 10^{23} ; \mathrm{M}_{\mathrm{K}}=39.1 \mathrm{~g} \cdot \mathrm{~mol}^{-1}$

## Solution:

a) N decreases, to $\mathrm{N}-1, \mathrm{Z}$ increases to $\mathrm{Z}+1$, A constant.
b) $N / Z \gg 1$
c) Activity (A): number of disintegrations per unit time $=$ decay rate. $A=N \lambda=N / \tau$, where $\tau$ is the mean lifetime
d)

Decay constant $\lambda=0.693 / \mathrm{t}_{1 / 2}=5.544 \cdot 10^{-10} \mathrm{y}^{-1}$
Amount of K atoms in the body: $250 \mathrm{~g}<>250 / 39.1=6.394 \mathrm{~mol} \mathrm{~K}<>3.85 \cdot 10^{24}$ atoms K .
Amount of ${ }^{40} \mathrm{~K}$ atoms in the body: $0.00012 \cdot 3.85 \cdot 10^{24}=4.62 \cdot 10^{20}$ atoms ${ }^{40} \mathrm{~K}$.
Activity $A=N \lambda=4.62 \cdot 10^{20} \cdot 5.544 \cdot 10^{-10}=2.56 \cdot 10^{11} \mathrm{~d} / \mathrm{y}$
Amount of energy released along $80 \mathrm{y}: 2.56 \cdot 10^{11} \mathrm{~d} / \mathrm{y} \cdot 1.311 \mathrm{MeV} \cdot 10^{6} \mathrm{eV} / \mathrm{MeV} \cdot 80$
$y=2.69 \cdot 10^{19} \mathrm{eV}<>4.3 \mathrm{~J}$.
Absorbed dose: $4.3 \mathrm{~J} / 80 \mathrm{~kg}=0.054 \mathrm{~Gy}$ <> 54 mGy .
2.- (1 point) Consider the following molecules $\mathrm{HBr}, \mathrm{CO}_{2}, \mathrm{SO}_{2}, \mathrm{XeF}_{4}$ :
a) (0.2 point) Write their Lewis structures.
b) ( 0.2 point) Indicate how many lone pairs has the central atom and describe the molecular geometry.
c) ( 0.2 point) Justify which of them have non zero dipolar moment.
d) ( 0.2 point) Justify which of them are water soluble.
e) ( 0.2 point) Which is the bond order for HBr ? Justify the answer.

Solution:
a)

H- ̈̈r:
$\ddot{\mathrm{O}}=\mathrm{C}=\ddot{\mathrm{O}}$
$\ddot{\mathrm{O}}=\ddot{\mathrm{S}}=\ddot{\mathrm{O}}$

b)

HBr 3 lone pairs; linear
$\mathrm{CO}_{2}$ no lone pairs, linear
$\mathrm{SO}_{2} 1$ lone pair, angular
$\mathrm{XeF}_{4} 2$ Ione pairs, square planar
c) $\mathrm{HBr}, \mathrm{SO}_{2}$ have non zero dipolar moment because of the unsymmetrical distribution of lone pairs
d) HBr and $\mathrm{SO}_{2}$ will be more polar so they will be more water soluble
e) H uses $1 \mathrm{~s}^{1}$ atomic orbital and Br one $4 \mathrm{p}^{1}$ of its five atomic orbitals to form a molecular sigma ( $\sigma$ ) bond. Since each atom contributes with one electron they will form a single $\sigma$ bond. The $\sigma^{*}$ antibonding molecular orbital will be empty so the bond order will be 1 .
3.- (1 point) Concerning thermochemistry answer the following questions:
a) ( 0.25 point) What is internal energy?

Internal Energy, E , of a system is that energy that only depends on the nature of the system and is independent on its position in any force field or its rest or motion state. Therefore Internal Energy is the sum of the kinetic energy of the molecules or atoms of the system (associated to translations, rotations and vibrations) and the potential energy associated to intermolecular forces.
b) ( 0.25 point) What is enthalpy?

Is the absorbed or released heat in a constant pressure process
c) ( 0.25 point) What are reversible and irreversible processes? Explain using a gas expansion process.

In a reversible expansion process, internal and external pressures differ only infinitesimally. That means that the process is done very slowly. $P_{\text {int }}=P_{\text {ext }}+d P$ or $P_{\text {ext }}=P_{\text {int }}-d P$.
In irreversible processes internal and external pressures are different and $\mathrm{P}_{\text {ext }}<\mathrm{P}_{\text {int }}$.
d) ( 0.25 point) We need to compress a gas inside a piston. How we do it with as little work as possible? In a reversible way since $\mathrm{w}_{\text {rev }}<\mathrm{w}_{\text {irr }}$.
4.- (1.4 points) A $258.3 \mathrm{~cm}^{3}$ chamber equipped with a piston contains $\mathrm{CH}_{4}$ at 10 atm . and $77^{\circ} \mathrm{C} .6 .4 \mathrm{~g}$ of $\mathrm{O}_{2}$ are injected in the chamber, being this amount more than needed for a complete combustion of methane. After combustion the system returns to the initial temperature and it is found 5 L of a gas mixture at an unknown pressure over a certain amount of liquid water.
a) ( 0.2 points) Balance the combustion equation.
b) ( 0.8 point) Find the amount of water in the gas mixture and the volume of liquid water.
c) ( 0.4 points)Calculate the volume percentage composition of the gas mixture after combustion.
Data: $\rho\left(\mathrm{H}_{2} \mathrm{O}_{\mathrm{L}}, 77^{\circ} \mathrm{C}\right)=0.978 \mathrm{~g} \cdot \mathrm{~cm}^{-3} ; \quad \mathrm{P}\left(\mathrm{H}_{2} \mathrm{O}_{\mathrm{g}}, 77^{\circ} \mathrm{C}\right)=314.1 \mathrm{mmHg} ; \mathrm{R}=0.082 \mathrm{~atm} \cdot \mathrm{~L} \cdot \mathrm{~mol}^{-1} \cdot \mathrm{~K}^{-1}$; $M\left(\mathrm{O}_{2}\right)=32 \mathrm{~g} \cdot \mathrm{~mol}^{-1} ; \mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)=18 \mathrm{~g} \cdot \mathrm{~mol}^{-1}$.

## Solution:

a) $\mathrm{CH}_{4}+2 \mathrm{O}_{2} \rightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}$
b) The amount of water vapour in the gas mixture can be calculated from the water vapour pressure $n\left(w_{g}\right)=P\left(w_{g}\right) V / R T=(314.1 / 760) \cdot 10 / 0.082 \cdot 350=0.072 \mathrm{~mol} \mathrm{H} \mathrm{H}_{\mathrm{g}}$
After combustion methane transforms completely into $\mathrm{CO}_{2}$ and water. The number of moles of $\mathrm{CH}_{4}$ is $\mathrm{n}_{\mathrm{M}}=10 \cdot 0.2583 / 0.082 \cdot 350=0.09$ moles of $\mathrm{CH}_{4}$, which is the same as the number of moles of $\mathrm{CO}_{2}\left(\mathrm{n}_{\mathrm{C}}\right)$. The number of moles of water (liquid plus vapour) will be $2 \cdot \mathrm{n}_{\mathrm{C}}=0.18$.
The amount of liquid water will be the difference between the total water and the water in gas phase $\mathrm{w}_{\mathrm{L}}=0.18-0.072=0.108 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}_{\mathrm{L}}<>0.108 \cdot 18=1.944 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}_{\mathrm{L}}<>1.944 / 0.978=1.988 \mathrm{~cm}^{3}$ $\mathrm{H}_{2} \mathrm{O}_{\mathrm{L}}$.
c) Oxygen: the initial amount of oxygen is $6.4 \mathrm{~g}<>6.4 / 32=0.2 \mathrm{~mol} \mathrm{O}_{2}$. Since combustion is complete, the amount of reacted oxygen is $2 \cdot n_{M}=2 \cdot 0.09=0.18 \mathrm{~mol} \mathrm{O}_{2}$. The amount of non reacted oxygen will be $0.2-0.18=0.02 \mathrm{~mol} \mathrm{O}_{2}$.
Methane: absent
Carbon dioxide: $\mathrm{n}_{\mathrm{C}}=0.09 \mathrm{~mol} \mathrm{CO}_{2}$
Water vapour $=0.072 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}_{\mathrm{g}}$.
Total number of moles in gas phase after combustion $n_{T}=0.02+0.09+0.072=0.182 \mathrm{~mol}$
$\% \mathrm{O}_{2}=0.02 / 0.182=10.98 \%$
$\% \mathrm{CO}_{2}=0.09 / 0.182=49.45 \%$
5.- (1.4 points) Water is added to 16.4 g of sodium acetate to prepare 500 mL of solution. Calculate:
a) (0.4 points) pH of the solution.
b) ( 0.6 points) The weight of acetic acid that must be added to obtain a pH of 5 ?
c) ( 0.4 point) The weight of solid silver nitrate $\left(\mathrm{AgNO}_{3}\right)$ we must add to the initial sodium acetate solution to begin precipitation of silver acetate $\left(\mathrm{AgCH}_{3} \mathrm{COO}\right)$.
Data: $M$ (acetic acid) $=60 \mathrm{~g} \cdot \mathrm{~mol}^{-1} ; ~ M$ (sodium acetate) $=82 \mathrm{~g} \cdot \mathrm{~mol}^{-1} ; \mathrm{K}_{\mathrm{a}}($ acetic acid $)=1.8 \cdot 10^{-5}$;
$\mathrm{M}\left(\mathrm{AgNO}_{3}\right)=170 \mathrm{~g} \cdot \mathrm{~mol}^{-1} ; \mathrm{K}_{\mathrm{s}}\left(\mathrm{AgCH}_{3} \mathrm{COO}\right)=1.94 \times 10^{-3}$.

## Solution:

a) $\mathrm{AcNa} \rightarrow \mathrm{Ac}^{-}+\mathrm{Na}^{+}$
$[\mathrm{AcNa}]=(16.4 \mathrm{~g} /(82 \mathrm{~g} / \mathrm{mol})) / 0.5 \mathrm{I}=0.4 \mathrm{M}$

|  | $\mathrm{Ac}^{-}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{AcH}+\mathrm{OH}^{-}$ |  |  |
| :--- | :--- | :---: | :---: |
| i) | 0.4 M | 0 | 0 |
| eq) | $0.4-\mathrm{x}$ | x | x |

$\mathrm{K}_{\mathrm{h}}=\mathrm{K}_{\mathrm{w}} / \mathrm{K}_{\mathrm{a}}=10^{-14} / 1.8 \cdot 10^{-5}=5.56 \cdot 10^{-10}=\mathrm{x}^{2} /(0.4-\mathrm{x}) \approx \mathrm{x}^{2} / 0.4 ; \mathrm{x}=\left(0.4 \cdot 5.56 \cdot 10^{-10}\right)^{1 / 2}=1.49 \cdot 10^{-5} \mathrm{M}$;
$\mathrm{pOH}=4.826 ; \mathrm{pH}=9.173$
b) Buffer
$\mathrm{pH}=\mathrm{pK}_{\mathrm{a}}-\log ([$ acid $] /[$ base $]) ; 5=4.74-\log ([\mathrm{AcH}] / 0.4) ;[\mathrm{AcH}]=0.222 \mathrm{M}$
$0.222(\mathrm{~mol} / \mathrm{L}) \cdot 0.5 \mathrm{~L} \cdot 60(\mathrm{~g} / \mathrm{mol})=6.66 \mathrm{~g}$ acetic acid
c) $\mathrm{AgNO}_{3} \rightarrow \mathrm{Ag}^{+}+\mathrm{NO}_{3}^{-}$
$\mathrm{Ag}^{+}+\mathrm{Ac}^{-} \rightarrow \mathrm{AgAc}_{(\mathrm{s})}$
$\mathrm{Ks}=\left[\mathrm{Ac}^{-}\right]\left[\mathrm{Ag}^{+}\right]=1.94 \times 10^{-3}$
$\left[\mathrm{Ag}^{+}\right]=\mathrm{Ks} /\left[\mathrm{Ac}^{-}\right]=1.94 \times 10^{-3} / 0.4=4.85 \cdot 10^{-3} \mathrm{M}$
$\mathrm{n}\left(\mathrm{Ag}^{+}\right)=4.85 \cdot 10^{-3} \mathrm{M} \cdot 0.5 \mathrm{~L}=2.425 \cdot 10^{-3} \mathrm{~mol}\left\langle>2.425 \cdot 10^{-3} \cdot 170=0.412 \mathrm{~g} \mathrm{AgNO}_{3}\right.$
6.- (1.4 points) Consider a cell in which the following reaction takes place:

$$
5 \mathrm{Fe}^{2+}(\mathrm{ac})+\mathrm{MnO}_{4}^{-}(\mathrm{ac})+8 \mathrm{H}^{+}(\mathrm{ac}) \leftrightarrow 5 \mathrm{Fe}^{3+}(\mathrm{ac})+\mathrm{Mn}^{2+}(\mathrm{ac})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{I})
$$

Platinum electrodes are introduced in both anode and cathode, a saline bridge connects the two electrodes and the electrodes are connected to a voltmeter.
a) ( 0.2 points) What is the standard potential of the cell?
b) ( 0.2 points) What reaction takes place in the anode and the cathode? What is the direction of electron movement through the external circuit? Draw a scheme of the cell.
c) ( 0.4 points) What is the equilibrium constant of the reaction at $25{ }^{\circ} \mathrm{C}$ ?
d) (0.6 points) What is the cell potential if $\left[\mathrm{H}^{+}\right]$is decreased from its standard value to $10^{-4} \mathrm{M}$ keeping constant the concentration of all other species?
Data: $\mathrm{E}^{0}\left(\mathrm{MnO}_{4}^{-} / \mathrm{Mn}^{2+}\right)=1.512 \mathrm{~V} ; \mathrm{E}^{0}\left(\mathrm{Fe}^{3+} / \mathrm{Fe}^{2+}\right)=0.771 \mathrm{~V}$

## Solution:

a) $\mathrm{Fe}^{2+}$ oxidizes into $\mathrm{Fe}^{3+}$ and $\mathrm{MnO}_{4}^{-}$reduces to $\mathrm{Mn}^{2+}$. The cell potential will be $\mathrm{E}^{0}\left(\mathrm{MnO}_{4}^{-} / \mathrm{Mn}^{2+}\right)$ $-\mathrm{E}^{0}\left(\mathrm{Fe}^{3+} / \mathrm{Fe}^{2+}\right)=1.512-0.771=0.741 \mathrm{~V}$.
b) $\mathrm{Fe}^{2+}$ oxidizes into $\mathrm{Fe}^{3+}$ in the anode and $\mathrm{MnO}_{4}^{-}$reduces to $\mathrm{Mn}^{2+}$ in the cathode. Electrons are produced in the anode ( $\mathrm{Fe}^{2+} / \mathrm{Fe}^{3+}$ electrode) and move to the cathode $\left(\mathrm{Mn}^{2+} / \mathrm{MnO}_{4}^{-}\right)$
c) The equilibrium constant of the redox reaction is given by

$$
\begin{aligned}
& E=E^{0}-\frac{0.0257}{n} \ln Q=E^{0}-\frac{0.059}{5} \log Q \text { at equilibriu } m=0 \text { and } Q=K \\
& K=10^{\frac{E^{0} n}{0.059}}=10^{\frac{0.739 \times 5}{0.059}}=4.24 \cdot 10^{62}
\end{aligned}
$$

d) $E=E^{0}-\frac{0.059}{5} \log \frac{\left[\mathrm{Mn}^{2+}\right] \cdot\left[\mathrm{Fe}^{3+}\right]^{5}}{\left[\mathrm{MnO}_{4}^{-}\right] \cdot\left[\mathrm{Fe}^{2+}\right]^{5} \cdot\left[\mathrm{H}^{+}\right]^{8}}=0.739-0.0118 \log \frac{1}{10^{-32}}=0.361 \mathrm{~V}$
7.- (1,2 point) Complete the following set of reactions and draw the stereoisomers of product B.

Solution: ( 0,2 points each correct product and 0.2 for stereoisomers)

(2R)-propane-1,2-diol

(2S)-propane-1,2-diol
8. (1,4 point) Product $\mathbf{A}$ is obtained reacting benzene with one mol of $\mathrm{CH}_{3} \mathrm{Cl}$ using $\mathrm{AlCl}_{3}$ as catalyst. A is subjected to the following set of reactions: a) $\mathrm{Br}_{2}$ in the presence of iron as catalyst giving a single product B because of steric hindrance, b) magnesium under anhydrous conditions (ether) giving product $\mathbf{C}$, c) carbon dioxide and subsequently water, giving the product $\mathbf{D}, \mathrm{d}$ ) thionyl chloride giving $\mathbf{E}$ which reacts with methylamine giving $\mathbf{F}$. Deduce the structural formulas of compounds $\mathbf{A}$ to $\mathbf{F}$.

## Solution:
